## **Project Report**

## Push Sum Algorithm:

Data in a tabular form:

| Time\Topology | Line  | Full | 2D     | 2Dimp |
|---------------|-------|------|--------|-------|
| 10            | 407   | 34   | 77     | 47    |
| 100           | 2113  | 353  | 1421   | 759   |
| 200           | 1623  | 560  | 2510   | 1117  |
| 300           | 6577  | 739  | 10852  | 1592  |
| 400           | 11828 | 985  | 26216  | 1605  |
| 500           | 13750 | 1224 | 48742  | 1551  |
| 700           | 20839 | 1588 | 80837  | 2323  |
| 1000          | 22334 | 2287 | 132298 | 2996  |

This table represents the time required to converge the program for different topologies when the number of actors are changed from the range 0 to 100.

When we plot the graph as shown in figure 1.1, I observed following outcomes.

- Line Topology takes most time to converge under any set of varying input.
- **Full Topology** converges rapidly under the varying input. I can see that it increases linearly as the number of actor's increases. So we can say that in the push sum algorithm time taken to converge by full topology is directly proportional to no of actors involved in the gossip.
- When the number of actors in the system increases we can see a drastic increase in the convergence time taken by **2D** topology.
- Even though number of actors increases the time taken to converge by **2D Impatient** increases slowly.

## • Asynchronous Gossip Data in a tabular form

| Time\Topology | Line | Full | 2D   | 2DImp |
|---------------|------|------|------|-------|
| 10            | 4    | 3    | 34   | 5     |
| 100           | 20   | 17   | 22   | 32    |
| 500           | 101  | 76   | 99   | 127   |
| 1000          | 166  | 92   | 141  | 122   |
| 2000          | 210  | 157  | 231  | 279   |
| 3000          | 256  | 143  | 286  | 248   |
| 5000          | 623  | 188  | 582  | 486   |
| 10000         | 712  | 487  | 2050 | 1590  |
| 20000         | -    | 522  | 7292 | 3712  |

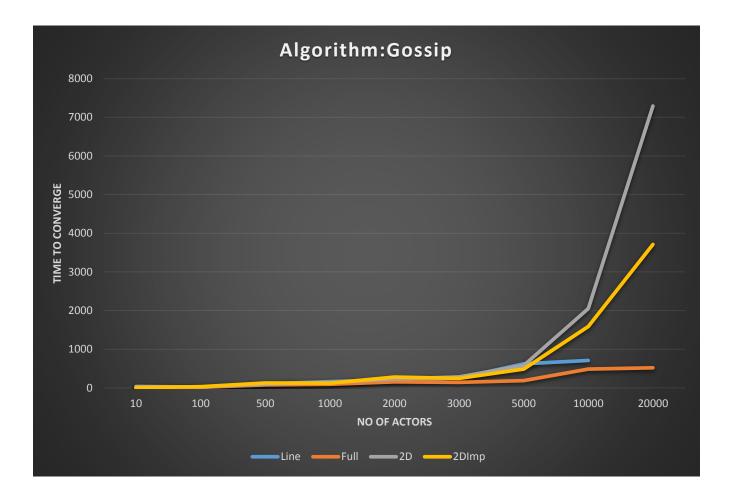

This table represents the time required to converge the program for different topologies when the number of actors are changed from the range 0 to 20000. Here each actor stops transmitting once it has heard the rumor 10 times.

When we plot the graph as shown in figure 1.2, I observed following outcomes:

- Line topology fail to converge when actors increased beyond 10000.
- **Full** topology is the fastest topology when asynchronous gossip is considered.
- **2D and 2D impatient** shows similar kind of charactaristics in the above table. But when compared against each other 2D impatient takes less time as it is sending message to random actor.

<u>Conclusion:</u> I have successfully simulated convergence of gossip and push sum algorithms using akka actors for the four different topologies.

For the big networks (actors >10000) with a gossip algorithm Full and 2D Imp topologies can be preferred over simple 2D and line.

Whereas in case of push sum, 2D imp topology is more efficient than other three topologies.

By looking at the outcome we can say that as the network increases the convergence of program becomes slow.
